# **Cloudmesh REST Interface for Virtual Clusters**

Gregor von Laszewski $^{1,*}$ , Fugang Wang $^1$ , and Badi Abdhul-Wahid $^1$ 

Draft v0.0.1, May 2, 2017

This document summarizes a number of objects that are instrumental for the interaction with Clouds, Containers, and HPC systems to manage virtual clusters. TBD

1.	INTRODUCTION	
In-	this document we summarize elementary objects that	are
	portant to for the NBDRA.	
1.1	. Lessons Learned	
TH	BD	
1.2	. Hybrid Cloud	
	•	$\overline{}$
TH	BD .	

To accelerate discussion among the team we use an approach to define objects and its interfaces by example. These examples are than taken in a later version of the document and a schema is generated from it. The schema will be added in its complete form to the appendix B. While focusing first on examples it allows us to speed up our design and simplifies

104

105

106

107

discussions of the objects and interfaces eliminating getting lost in complex syntactical specifications. The process and specifications used in this document will also allow us to automatically create a implementation of the objects that can be integrated into a reference architecture as provided by for example the cloudmesh client and rest project [?].

An example object will demonstrate our approach. The following object defines a JSON object representing a user.

```
Listing 1.1: User profile

{

    "profile": {
        "description": "The Profile of a user",
        "uuid": "jshdjkdh...",
        "context:": "resource",
        "email": "laszewski@gmail.com",
        "firstname": "Gregor",
        "lastname": "von Laszewski",
        "username": "gregor"
}

}
```

Such an object can be transformed to a schema specification while introspecting the types of the original example. The resulting schema object follows the Cerberus [?] specification and looks for our object as follows:

```
profile = {
   'description': { 'type': 'string'},
   'email': { 'type': 'email' },
   'firstname': { 'type': 'string'},
   'lastname': { 'type': 'string' },
   'username': { 'type': 'string' }
}
```

As mentioned before, the AppendixB will list the schema that is automatically created from the definitions.

# 1.4. Tools to Create the Specifications

The tools to create the schema and object are all available opensource and are hosted on github. It includes the following repositories:

# cloudmesh.common

https://github.com/cloudmesh/cloudmesh.common

# cloudmesh.cmd5

https://github.com/cloudmesh/cloudmesh.cmd5

#### cloudmesh.rest

https://github.com/cloudmesh/cloudmesh.rest

# cloudmesh/evegenie

https://github.com/cloudmesh/evegenie

# 1.5. Installation of the Tools

The current best way to install the tools is from source. A convenient shell script conducting the install is located at:

TBD

Once we have stabilized the code the package will be available from pypi and can be installed as follows:

```
pip install cloudmesh.rest
pip install cloudmesh.evengine
```

#### 142 1.6. Document Creation

It is assumed that you have installed all the tools. TO create the document you can simply do

git clone https://github.com/cloudmesh/cloudmesh.resttdcccdcloudmesh.rest/doccsmake

This will produce in that directory a file called object.pdf containing this document.

# 1.7. Conversion to Word

We found that it is inconvenient for the developers to maintain this document in Microsoft Word as typically is done for other documents. This is because the majority of the information contains specifications that are directly integrated in a reference implementation, as well as that the current majority of contributors are developers. We would hope that editorial staff provides direct help to improve this document, which even can be done through the github Web interface and does not require any access either to the tools mentioned above or the availability of LATEX.

The files are located at:

 https://github.com/cloudmesh/cloudmesh.rest/tree/master/ docs

# 1.8. Interface Compliancy

Due to the extensibility of our interfaces it is important to introduce a terminology that allows us to define interface compliancy. We define it as follows

**Full Compliance:** These are reference implementations that provide full compliance to the objects defined in this document. A version number will be added to assure the snapshot in time of the objects is associated with the version. This reference implementation will implement all objects.

Partially Compliance: These are reference implementations that provide partial compliance to the objects defined in this document. A version number will be added to assure the snapshot in time of the objects is associated with the version. This reference implementation will implement a partial list of the objects. A document is accompanied that lists all objects defined, but also lists the objects that are not defined by the reference architecture.

**Full and extended Compliance:** These are interfaces that in addition to the full compliance also introduce additional interfaces and extend them.

# 2. USER AND PROFILE

In a multiuser environment we need a simple mechanism of associating objects and data to a particular person or group. While we do not want to replace with our efforts more elaborate solutions such as proposed by eduPerson (http://software.internet2.edu/eduperson/internet2-mace-dir-eduperson-201602.html) or others [?], we need a very simple way of distinguishing users. Therefore we have introduced a number of simple objects including a profile and a user.

#### 2.1. Profile

A profile is simple the most elementary information to distinguish a user profile. It contains name and e-mail information. It may have an optional uuid and/or use a unique e-mail to distinguish a user.

```
Listing 2.1: User profile

{
    "profile": {
        "description": "The Profile of a user",
        "uuid": "jshdjkdh...",
        "context:": "resource",
        "email": "laszewski@gmail.com",
        "firstname": "Gregor",
        "lastname": "von Laszewski",
        "username": "gregor"
    }
}
```

#### 2.2. User

In contrast to the profile a user contains additional attributs that define the role of the user within the system.

```
Listing 2.2: user

{

"user": {

"uuid": "jshdjkdh...",

"context:": "resource",

"email": "laszewski@gmail.com",

"firstname": "Gregor",

"lastname": "von Laszewski",

"username": "gregor",

"roles": ["admin", "user"]

}

}

}
```

# 2.3. Organization

An important concept in many applications is the management of a roup of users in a virtual organization. This can be achieved through two concepts. First, it can be achieved while useing the profile and user resources itself as they contain the ability to manage multiple users as part of the REST interface. The second concept is to create a virtual organization that lists all users of this virtual organization. The third concept is to introduce groups and roles either as part of the user definition or as part of a simple list similar to the organization

```
Listing 2.3: user

{

"organization": {

"users": [

"objectid:user"

5

]

}
}
```

247

248

249

250 251

252

253

254

255

256

257

258

259

261

264

265

267

274

#### 2.4. Group/Role

215

216

217

219

221

222

A group contains a number of users. It is used to manage authorized services.

```
Listing 2.4: group
    "group": {
       "name": "users",
       "description": "This group contains all
    users",
       "users": [
         "objectid:user"
      ٦
}
```

A role is a further refinement of a group. Group members can have specific roles. A good example is that ability to formulate a group of users that have access to a repository. However the role defines more specifically read and write privileges to the data within the repository.

```
Listing 2.5: role
    "role": {
      "name": "editor",
      "description": "This role contains all
    editors",
       "users": [
         "objectid:user"
}
```

# 3. DATA

226

227

228

229

230

231

232

233

234

235

236

237

238

239

240

241

242

243

Data for Big Data applications are delivered through data providers. They can be either local providers contributed by a user or distributed data providers that refer to data on the internet. At this time we focus on an elementary set of abstractions related to data providers that offer us to utilize variables, files, virtual data directories, data streams, and data filters.

Variables are used to hold specific contents that is associated in programming language as a variable. A variable has a name, value and type.

Default is a special type of variable that allows adding of a 270 context. defaults can than created for different contexts. 271

Files are used to represent information collected within the 273 context of classical files in an operating system.

Streams are services that offer the consumer a stream of data. 276 Streams may allow the initiation of filters to reduce the amount of data requested by the consumer Stream Filters operate in streams or on files converting them to streams

**Batch Filters** operate on streams and on files while working in the background and delivering as output Files

Virtual directories and non-virtual directories are collection of files that organize them. For our initial purpose the distinction between virtual and non-virtual directories is non-essential and we will focus on abstracting all directories to be virtual. This could mean that the files are physically hosted on different disks. However, it is important to note that virtual data directories can hold more than files, they can also contain data streams and data filters.

variables are used to store a simple values. Each variable can have a type. The variable value format is defined as string to allow maximal probability. The type of the value is also provided.

```
Listing 3.1: var
{
  "var": {
    "name": "name of the variable",
    "value": "the value of the variable as
    string",
    "type": "the datatype of the variable such
    as int, str, float, ..."
  }
}
```

#### 3.2. Default

A default is a special variable that has a context associated with it. This allow su to define values that can be easily retrieved based on its context. A good example for a default would be the image name for a cloud where the context is defined by the cloud name.

```
Listing 3.2: default
{
  "default": {
    "value": "string",
    "name": "string",
    "context": "string
                         - defines the context
    of the default (user, cloud, ...)"
  }
}
```

A file is a computer resource allowing to store data that is being processed. The interface to a file provides the mechanism to appropriately locate a file in a distributed system. Identification include the name, and andpoint, the checksum and the size. Additional parameters such as the lasst access time could be stored also. As such the Interface only describes the location of the file

The **file** object has *name*, *endpoint* (location), *size* in GB, MB, Byte, *checksum* for integrity check, and last *accessed* timestamp.

```
Listing 3.3: file
{
    "file": {
         "name": "report.dat",
```

```
"endpoint":

"file://gregor@machine.edu:/data/report.dat",

"checksum":

{"md5":"8c324f12047dc2254b74031b8f029ad0"},

"accessed": "1.1.2017:05:00:00:EST",

"created": "1.1.2017:05:00:00:EST",

"modified": "1.1.2017:05:00:00:EST",

"size": ["GB", "Byte"]
}
}
}
```

#### 3.4. File Alias

279

281

282

284

285

286

287

289

290

291

292

293

A file could have one alias or even multiple ones.

```
Listing 3.4: file alias

{
    "file_alias": {
        "alias": "report-alias.dat",
        "name": "report.dat"
}
}
```

#### 3.5. Replica

In many distributed systems, it is of importance that a file can be replicated among different systems in order to provide faster access. It is important to provide a mechanism that allows to trace the pedigree of the file while pointing to its original source

```
Listing 3.5: replica
      "replica": {
        "name": "replica_report.dat",
        "replica": "report.dat",
        "file://gregor@machine.edu:/data/replica_report.da
        "checksum": {
             "md5":
        "8c324f12047dc2254b74031b8f029ad0"
        },
        "accessed": "1.1.2017:05:00:00:EST",
        "size": [
10
                                                             305
11
           "GB",
           "Byte"
                                                             306
12
                                                             307
        ٦
13
      }
                                                             308
14
   }
                                                             309
```

# 3.6. Virtual Directory

A collection of files or replicas. A virtual directory can contain an number of entities cincluding files, streams, and other virtual directories as part of a collection. The element in the collection can either be defined by uuid or by name.

```
"endpoint": "http://.../data/",
"protocol": "http",
"collection": [
    "report.dat",
    "file2"
]

10
}
}
```

#### 3.7. Database

297

298

A **database** could have a name, an *endpoint* (e.g., host:port), and protocol used (e.g., SQL, mongo, etc.).

```
Listing 3.7: database

{

"database": {

"name": "data",

"endpoint": "http://.../data/",

"protocol": "mongo"

}

}
```

#### 3.8. Stream

A stream proveds a stream of data while providing information about rate and number of items exchanged while issuing requests to the stream. A stream my return data items in a specific fromat that is defined by the stream.

```
Listing 3.8: stream

{

"stream": {

"name": "name of the variable",

"format": "the format of the data

da 
exchanged in the stream",

"attributes": {

"rate": 10,

"limit": 1000

}

}

}

}
```

Examples for streams could be a stream of random numbers but could also include more complex formats such as the retrieval of data records.

Services can subscribe, unsubscribe from a stream, while also applying filters to the subscribed stream.

```
Listing 3.9: filter

{

"filter": {

"name": "name of the filter",

"function": "the function of the data

exchanged in the stream"

}

}
```

Filter needs to be refined

# 313 4. IAAS

317

318

In this section we are defining resources related to Infrastructure as a Service frameworks. This includes specific objects useful for OpenStack, Azure, and AWS, as well as others.

#### 4.1. Openstack

#### 4.1.1. Openstack Flavor

```
Listing 4.1: openstack flavor

{

"openstack_flavor": {

"os_flv_disabled": "string",

"uuid": "string",

"os_flv_ext_data": "string",

"ram": "string",

"os_flavor_acces": "string",

"vcpus": "string",

"swap": "string",

"rxtx_factor": "string",

"disk": "string"

}

}
```

# 320 4.1.2. Openstack Image

```
Listing 4.2: openstack image
    {
      "openstack_image": {
        "status": "string",
        "username": "string",
        "updated": "string",
        "uuid": "string",
        "created": "string",
        "minDisk": "string",
        "progress": "string",
        "minRam": "string",
10
        "os_image_size": "string",
11
        "metadata": {
12
          "image_location": "string",
13
          "image_state": "string",
14
          "description": "string",
15
          "kernel_id": "string",
16
          "instance_type_id": "string",
17
          "ramdisk_id": "string",
18
19
          "instance_type_name": "string",
20
          "instance_type_rxtx_factor": "string",
          "instance_type_vcpus": "string",
21
          "user_id": "string",
22
          "base_image_ref": "string",
23
          "instance_uuid": "string",
24
          "instance_type_memory_mb": "string",
25
          "instance_type_swap": "string",
26
          "image_type": "string",
27
28
          "instance_type_ephemeral_gb": "string",
29
          "instance_type_root_gb": "string",
          "network_allocated": "string",
30
31
          "instance_type_flavorid": "string",
          "owner_id": "string"
32
        }
33
      }
34
```

```
5 }
```

# 4.1.3. Openstack Vm

```
Listing 4.3: openstack vm
    {
      "openstack_vm": {
        "username": "string",
        "vm_state": "string",
        "updated": "string",
        "hostId": "string",
        "availability_zone": "string",
        "terminated_at": "string",
        "image": "string",

# 6. VIRTUAL CLUSTER

#### 6.1. Cluster

341

345

The cluster object has name, label, endpoint and provider. The *endpoint* defines.... The *provider* defines the nature of the cluster, e.g., its a virtual cluster on an openstack cloud, or from AWS, or a bare-metal cluster.

```
Listing 6.1: cluster
                                                      </>
    {
      "cluster": {
        "label": "c0",
        "endpoint": {
           "passwd": "secret",
           "url": "https"
        },
         "name": "myCLuster",
        "provider": [
           "openstack",
10
           "aws",
11
12
           "azure",
           "eucalyptus"
13
14
      }
15
   }
```

#### 6.2. Compute Resource

347

348

349

350

351

352

355

356

357

360

361

363

365

366

367

368

369

372

373

374

375

377

378

379

380

381

382

An important concept for big data analysis it the representation of a compute resource on which we execute the analysis. We define a compute resource by name and by endpoint. A compute resource is an abstract concept and can be instantiated through virtual machines, containers, or bare metal resources. This is defined by the "kind" of the compute resource

**compute\_resource** object has attribute *endpoint* which specifies ... The *kind* could be *baremetal* or *VC*.

```
Listing 6.2: compute resource

{

    "compute_resource": {

        "name": "Compute1",

        "endpoint": "http://.../cluster/",

        "kind": "baremetal"

}

}
```

#### 6.3. Computer

This defines a **computer** object. A computer has name, label, IP address. It also listed the relevant specs such as memory, disk size, etc.

```
Listing 6.3: computer

{
    "computer": {
        "ip": "127.0.0.1",
        "name": "myComputer",
        "memoryGB": 16,
        "label": "server-001"
    }
}
```

# 6.4. Compute Node

A node is composed of multiple components:

- 1. Metadata such as the name or owner.
- 2. Physical properties such as cores or memory.
- Configuration guidance such as create\_external\_ip, security\_groups, or users.

The metadata is associated with the node on the provider end (if supported) as well as in the database. Certain parts of the metadata (such as owner) can be used to implement access control. Physical properties are relevant for the initial allocation of the node. Other configuration parameters control and further provisioning.

In the above, after allocation, the node is configured with a user called hello who is part of the wheel group whose account can be accessed with several SSH identities whose public keys are provided (in authorized\_keys).

Additionally, three ssh keys are generated on the node for the hello user. The first uses the ed25519 cryptographic method with a password read in from a GPG-encrypted file on the Command and Control node. The second is a 4098-bit RSA key also password-protected from the GPG-encrypted

file. The third key is copied to the remote node from an encrypted file on the Command and Control node.

This definition also provides a security group to control access to the node from the wide-area-network. In this case all ingress and egress TCP and UDP traffic is allowed provided they are to ports 22 (SSH), 443 (SSL), and 80 and 8080 (web).

```
Listing 6.4: node
      "node_new": {
         "authorized_keys": [
           "ssh-rsa AAAA...",
           "ssh-ed25519 AAAA...",
           "...etc"
        ],
         "name": "example-001",
         "external_ip": "",
         "loginuser": "root",

70
    }
```

# 6.5. Virtual Cluster

392

393

394

395

397

399

A virtual cluster is an agglomeration of virtual compute nodes that constitute the cluster. Nodes can be assembled to be baremetal, virtual machines, and containers. A virtual cluster contains a number of virtual compute nodes.

```
Listing 6.5: virtual cluster

{

    "virtual_cluster": {
        "name": "myvc",
        "frontend": "objectid:virtual_machine",
        "nodes": [
            "objectid:virtual_machine"
        ]
    }
}
```

# 6.6. Virtual Compute node

```
Listing 6.6: virtual compute node
      "virtual_compute_node": {
        "name": "data",
        "endpoint": "http://.../cluster/",
        "metadata": {
          "experiment": "exp-001"
        },
        "image": "Ubuntu-16.04",
        "ip": [
          "TBD"
10
        ],
11
        "flavor": "TBD",
12
        "status": "TBD"
13
14
   }
```

# 6.7. Virtual Machine

Virtual Machine Virtual machines are an emulation of a computer system. We are maintaining a very basic set of infor-

mation. It is expected that through the endpoint the virtual machine can be introspected and more detailed information can be retrieved.

```
Listing 6.7: virtual machine
      "virtual_machine" :{
        "name": "vm1",
        "ncpu": 2,
        "RAM": "4G",
        "disk": "40G",
        "nics": ["objectid:nic"
        "OS": "Ubuntu-16.04",
        "loginuser": "ubuntu",
11
        "status": "active",
12
        "metadata":{
13
        "authorized_keys": [
14
           "objectid:sshkey"
15
        ]
16
17
   }
```

#### 6.8. Mesos

```
Refine
    Listing 6.8: mesos
      "mesos-docker": {
        "instances": 1,
         "container": {
          "docker": {
             "credential": {
               "secret": "my-secret",
               "principal": "my-principal"
             "image": "mesosphere/inky"
11
          },
          "type": "MESOS"
12
        },
13
        "mem": 16.0,
14
        "args": [
15
          "argument"
16
17
18
        "cpus": 0.2,
         "id": "mesos-docker"
19
20
   }
21
```

# 7. CONTAINERS

# 7.1. Container

409

411

412

This defines **container** object.

```
Listing 7.1: container

{
    "container": {
    "name": "container1",
```

```
"endpoint": "http://.../container/",
        "ip": "127.0.0.1",
        "label": "server-001",
        "memoryGB": 16
    }
}
```

# 7.2. Kubernetes

Listing 7.2: kubernetes

REFINE 416

```
{
      "kubernetes": {
         "kind": "List",
         "items": [
           {
             "kind": "None",
             "metadata": {
               "name": "127.0.0.1"
             },
             "status": {
10
                "capacity": {

                    "password": "secret"
  53
  54
  55
            ]
  56
         }
  57
       }
  5
418
```

# 8. DEPLOYMENT

#### 8.1. Deployment

420

421

A **deployment** consists of the resource *cluster*, the location provider, e.g., AWS, OpenStack, etc., and software stack to be 422 deployed (e.g., hadoop, spark). 423

```
Listing 8.1: deployment
        "deployment": {
             "cluster": [{ "name": "myCluster"},
                          { "id" : "cm-0001"}
                         ],
             "stack": {
                 "layers": [
                      "zookeeper",
                      "hadoop",
                      "spark",
10
11
                      "postgresql"
12
                 ],
                  "parameters": {
13
                      "hadoop": {
14
         "zookeeper.quorum": [ "IP", "IP", "IP"]
15
16
                 }
17
            }
18
        }
   }
```

# 9. MAPREDUCE

# 9.1. Hadoop

424

425

426

427

428

429

430

A **hadoop** definition defines which *deployer* to be used, the parameters of the deployment, and the system packages as requires. For each requirement, it could have attributes such as the library origin, version, etc.

```
Listing 9.1: hadoop
  "hadoop": {
    "deployers": {
      "ansible":
    "git://github.com/cloudmesh_roles/hadoop"
    },
    "requires": {
      "java": {
        "implementation": "OpenJDK",
        "version": "1.8",
```

441

443

445

446

447

448

449

450

451

452

455

456

```
"zookeeper": "TBD",
  10
                "supervisord": "TBD"
  11
             }
  12
                                                                442
          },
  13
           "parameters": {
  14
             "num_resourcemanagers": 1,
  15
             "num_namenodes": 1,
  16
  17
             "use_yarn": false,
             "use_hdfs": true,
  18
             "num_datanodes": 1,
  19
             "num_historyservers": 1,
  20
  21
             "num_journalnodes": 1
  22
  23
        }
      }
  24
432
```

#### 9.2. Mapreduce

433

This defines a mapreduce deployment with its layered com-434 ponents. 435

```
Listing 9.2: mapreduce
        "mapreduce": {
            "layers": [
                 "hadoop"
            ],
            "hdfs_datanode": "IP ADDRESS",

493

494

495

496

497

498

499

500

We invite you to contribute to this paper and its discussion to improve it. Improvements can be done with pull requests. We suggest you do *small* individual changes to a single section and object rather than large changes as this allows us to integrate the changes individually and comment on your contribution via github.

Once contributed we will appropriately acknoledge you either as contributor or author. Please discuss with us how we best acknowledge you.

# D. USING THE CLOUDMESH REST SERVICE

Components are written as YAML markup in files in the resources/samples directory.

For example: 503

```
Listing D.1: profile
        "profile": {
           "description": "The Profile of a user",
           "uuid": "jshdjkdh...",
           "context:": "resource",
           "email": "laszewski@gmail.com",
           "firstname": "Gregor",
           "lastname": "von Laszewski",
                                                              513
           "username": "gregor"
                                                              514
  10
      }
  1
                                                              516
504
                                                              517
```

# **D.1. Element Definition**

Each resource should have a description entry to act as documentation. The documentation should be formated as reStructuredText. For example:

#### D.2. Yaml

505

506

507

```
entry = yaml.read(''')
                                                       522
profile:
  description: |
                                                       523
    A user profile that specifies general information
    about the user
  email: laszewski@gmail.com, required
  firtsname: Gregor, required
                                                       526
  lastname: von Laszewski, required
  height: 180

```

```
cms schema FILENAME --format=mongo -o OUTPUT
cms schema FILENAME --format=cerberus -o OUTPUT
cms schema FILENAME --format=yaml -o OUTPUT
```

reads FILENAME in cloudmesh notation and returns format

```
cms schema FILENAME --input=evegenie -o OUTPUT
  reads eavegene example and create settings for eve
```

#### F.1. Defining Elements for the REST Service

To manage a large number of elements defined in our REST service easily, we manage them trhough definitions in yaml files. To generate the appropriate settings file for the rest service, we can use teh following command:

```
cms admin elements <directory> <out.json>
```

where

520 521

529

536

537

539

540

541

- <directory>: directory where the YAML definitions re-
- <out.json>: path to the combined definition

For example, to generate a file called all.json that integrates all yml objects defined in the directory resources/samples you can use the following command:

```
cms elements resources/samples all.json
```

#### F.2. DOIT

cms schema spec2tex resources/specification resources/tex

#### F.3. Generating service

With evegenie installed, the generated JSON file from the above step is processed to create the stub REST service definitions.

With the cloudmesh REST framework it is easy to create REST services while defining the resources in the service easily with examples. The service is based on eve and the examples are defined in yml to be converted to json and from json with 605 evegenie into a valid eve settings file.

Thus oyou can eother wite your examples in yaml or in json. The resources are individually specified in a directory. The directory can contain multiple resource files. We recomment that for each resource you define your own file. Conversion of the specifications can be achieved with the schema 610 command.

# H.3. Yaml Specification

Let us first introduce you to a yaml specification. Let us assume that your yaml file is called profile.yaml and located in a directory called 'example':

```
profile:
565
      description: The Profile of a user
566
      email: laszewski@gmail.com
567
      firstname: Gregor
568
      lastname: von Laszewski
569
      username: gregor
570
```

As eve takes json objects as default we need to convert it first to json. This is achieved wih:

```
cd example
cms schema convert profile.yml profile.json
```

This will provide the json file profile.json as Listed in the next section

#### H.4. Json Specification

A valid json resource specification looks like this:

```
{
  "profile": {
    "description": "The Profile of a user",
    "email": "laszewski@gmail.com",
    "firstname": "Gregor",
    "lastname": "von Laszewski",
    "username": "gregor"
  }
}
```

# H.5. Conversion to Eve Settings

The json files in the ~/sample directory need now to be converted to a valid eve schema. This is achieved with tow commands. First, we must concatenate all json specified resource examples into a single json file. We do this with:

```
cms schema cat . all.json
```

As we assume you are in the samples directory, we use a 644 . for the current location of the directory that containes the samples. Next, we need to convert it to the settings file. THis can be achieved with the convert program when you specify a json file:

```
cms schema convert all.json
```

THe result will be a eve configuration file that you can use to start an eve service. The file is called all.settings.py

#### H.5.1. Managing Mongo

Next you need to start the mongo service with

```
cms admin mongo start
```

You can look at the status and information about the service with:

```
cms admin mongo info
cms admin mongo status
```

If you need to stop the service you can use:

cms admin mongo stop

# H.5.2. Manageing Eve

Now it is time to start the REST service. THis is done in a separate window with the following commands:

```
cms admin settings all.settings.json
cms admin rest start
```

The first command coppies the settings file to

```
~/cloudmesh/eve/settings.py
```

This file is than used by the start action to start the eve service. Please make sure that you execute this command in a separate window, as for debugging purposses you will be able to monitor this way interactions with this service

```
Testing - OLD ~
```

```
# install mongo and eve
make setup
make install
             # installs the code and integrates it into cmd5
make deploy
make test
```

classes lessons rest.rst

# I. REST WITH EVE

#### I.1. Overview of REST

REST stands for REpresentational State Transfer. REST is an architecture style for designing networked applications. It is based on stateless, client-server, cacheable communications protocol. Although not based on http, in most cases, the HTTP protocol is used. In contrast to what some others write or say, REST is not a standard.

RESTful applications use HTTP requests to:

- post data: while creating and/or updating it,
- read data: while making queries, and
- · delete data.

Hence REST uses HTTP for the four CRUD operations:

- Create
- Read
- Update
- Delete

As part of the HTTP protocol we have methods such as GET, PUT, POST, and DELETE. These methods can than be used to implement a REST service. As REST introduces collections and items we need to implement the CRUD functions for them. The semantics is explained in the Table illustrationg how to implement them with HTTP methods.

700

701

702

703

Now that we have outlined the basic functionality that we need, we lke to introduce you to Eve that makes this process rather trivial. We will provide you with an implementation example that showcases that we can create REST services without writing a single line of code. The code for this is located at https://github.com/cloudmesh/rest

This code will have a master branch but will also have a dev branch in which we will add gradually more objects. Objects in the dev branch will include:

- · virtual directories
- virtual clusters
- job sequences
- inventories

;You may want to check our active development work in the dev branch. However for the purpose of this class the 719 master branch will be sufficient.

# I.2.1. Installation

First we havt to install mongodb. The instalation will depend on your operating system. For the use of the rest service it 723 is not important to integrate mongodb into the system upon 724 reboot, which is focus of many online documents. However, for us it is better if we can start and stop the services explicitly for now.

On ubuntu, you need to do the following steps:

On windows 10, you need to do the following steps:

elect Windows 10. YOu could be using the online documentation

TO BE CONTRIBUTED BY THE STUDENTS OF THE CLASS as homeworkevegenion

provided by starting it on Windows, or rinning it in 732a

On OSX you can use homebrew and install it with:

brew update

brew install mongodb

# In future we may want to add ssl authentication in which case

need to install it as follows:

brew install mongodb -with-openssl

# I.2.2. Starting the service

We have provided a convenient Makefile that currently only works for OSX. It will be easy for you to adapt it to Linux. Certainly you can look at the targes in the makefile and replicate them one by one. Improtaht targest are deploy and test.

When using the makefile you can start the services with:

# make deploy

IT will start two terminals. IN one you will see the mongo service, in the other you will see the eve service. The eve service will take a file called sample.settings.py that is base on sample json for the start of the eve service. The mongo servide is configured in suc a wahy that it only accepts incimming connections from the local host which will be suffiicent fpr our case. The mongo data is written into the \$USER/.cloudmesh directory, so make sure it exists.

To test the services you can say:

YOu will se a number of json text been written to the screen.

# I.3. Creating your own objects

The example demonstrated how easy it is to create a mongodb and an eve rest service. Now lets use this example to creat your own. FOr this we have modified a tool called evegenie to install it onto your system.

The original documentation for evegenie is located at:

http://evegenie.readthedocs.io/en/latest/

However, we have improved evegenie while providing a commandline tool based on it. The improved code is located at:

· https://github.com/cloudmesh/evegenie

You clone it and install on your system as follows:

```
cd ~/github
git clone https://github.com/cloudmesh/evegenie
cd evegenie
python setup.py install
pip install .
```

This shoull install in your system evegenie. YOu can verify this by typing:

which evegenie

TO BE CONTRIBUTED BY THE STUDENTS OF THE CLASS as homework of you see the path evegenie is installed. With evegenie installed its usaage is simple:

> dbsager: container. evegenie --help evegenie FILENAME

It takes a json file as input and writes out a settings file for the use in eve. Lets assume the file is called sample.json, than the settings file will be called sample.settings.py. Having the evegenie programm will allow us to generate the settings files easily. You can include them into your project and leverage the Makefile targets to start the services in your project. In case you generate new objects, make sure you rerun evegenie, kill all previous windows in whcih you run eve and mongo and restart. In case of changes to objects that you have designed and run previously, you need to also delete the mongod database.

# I.4. Towards cmd5 extensions to manage eve and mongo

Naturally it is of advantage to have in cms administration commands to manage mongo and eve from cmd instead of targets in the Makefile. Hence, we propose that the class develops such an extension. We will create in the repository the extension called admin and hobe that students through collaborative work and pull requests complete such an admin command.

The proposed command is located at:

 https://github.com/cloudmesh/rest/blob/master/ cloudmesh/ext/command/admin.py

842

843

844

845

846

850

851

852

853

855

It will be up to the class to implement such a command. 810 Please coordinate with each other.

The implementation based on what we provided in the Make file seems straight forward. A great extensinion is to load the objects definitions or eve e.g. settings.py not from 813 the class, but forma place in .cloudmesh. I propose to place the file at:

```
.cloudmesh/db/settings.py
```

the location of this file is used whne the Service class is 817 initialized with None. Prior to starting the service the file 818 needs to be copied there. This could be achived with a set 819 commad. classes lesson python cmd5.rst

CMD is a very useful package in python to create command line shells. However it does not allow the dynamic integration of newly defined commands. Furthermore, addition to cmd need to be done within the same source tree. To simplify 826 developping commands by a number of people and to have a dynamic plugin mechnism, we developed cmd5. It is a rewrite on our ealier effords in cloudmesh and cmd3.

#### J.1. Resources

The source code for cmd5 is located in github:

https://github.com/cloudmesh/cmd5

Installation from source -

We recommend that you use a virtualenv either with virtualenv or pyenv. This can be either achieved vor virtualenv with:

virtualenv ~/ENV2

or for pyenv, with:

pyenev virtualenv 2.7.13 ENV2

Now you need to get two source directories. We assume yo place them in ~/github:

```
mkdir ~/github
789
    cd ~/github
790
```

```
git clone https://github.com/cloudmesh/common.git
git clone https://github.com/cloudmesh/cmd5.git
git clone https://github.com/cloudmesh/extbar.git
```

cd ~/github/common 796

python setup.py install

pip install . 798

cd ~/github/cmd5

python setup.py install 801 pip install . 802

cd ~/github/extbar 804 805

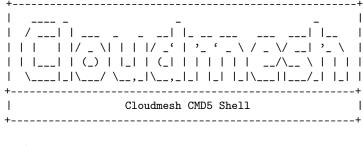

python setup.py install pip install .

The cmd5 repository contains the shell, while the extbar directory contains the sample to add the dynamic commands 858 foo and bar.

#### J.2. Execution

To run the shell you can activate it with the cms command. cms stands for cloudmesh shell:

It will print the banner and enter the shell:

To see the list of commands you can say

cms> help

To see the manula page for a specific command, please use:

help COMMANDNAME

# J.3. Create your own Extension

One of the most important features of CMD5 is its ability to extend it with new commands. This is done via packaged name spaces. This is defined in the setup.py file of your enhancement. The best way to create an enhancement is to take a look at the code in

https://github.com/cloudmesh/extbar.git

Simply copy the code and modify the bar and foo commands to fit yor needs.

make sure you are not copying the .git directory. Thus we recommend that you copy it explicitly file by file or directory by directory

It is important that all objects are defined in the command itself and that no global variables be use in order to allow each shell command to stand alone. Naturally you should develop API libraries outside of the cloudmesh shell command and reuse them in order to keep the command code as small as possible. We place the command in:

cloudmsesh/ext/command/COMMANDNAME.py

An example for the bar command is presented at:

 https://github.com/cloudmesh/extbar/blob/master/ cloudmesh/ext/command/bar.py

It shows how simple the command definition is (bar.py):

```
from __future__ import print_function
from cloudmesh.shell.command import command
from cloudmesh.shell.command import PluginCommand
```

class BarCommand(PluginCommand):

```
860
         def do_bar(self, args, arguments):
861
              11 11 11
862
863
              ::
                Usage:
864
                       command -f FILE
                       command FILE
866
                       command list
867
                This command does some useful things.
868
                Arguments:
869
                    FILE
                             a file name
870
                Options:
871
                     -f
                              specify the file
872
              print(arguments)
874
```

An important difference to other CMD solutions is that our commands can leverage (besides the standrad definition), docopts as a way to define the manual page. This allows us to use arguments as dict and use simple if conditions to interpret the command. Using docopts has the advantage that contributors are forced to think about the command and its options and document them from the start. Previously we used not to use docopts and argparse was used. However we noticed that for some contributions the lead to commands that were either not properly documented or the developers delivered ambiguous commands that resulted in confusion and wrong ussage by the users. Hence, we do recommend that you use docopts.

The transformation is enabled by the @command decorator that takes also the manual page and creates a proper help message for the shell automatically. Thus there is no need to introduce a separate help method as would normally be needed in CMD.
